November 2024

# What are Higher Order Methods?

## Definition

Higher order methods have truncation errors exceeding 2

- Fourth order finite-difference:

$$\left. \frac{\partial u}{\partial x} \right|_{x_i} = \frac{-u_{i+2} + 8u_{i+1} - 8u_{i-1} + u_{i-2}}{12\Delta x} + \frac{\Delta x^4}{30} \left. \frac{\partial^5 u}{\partial x^5} \right|_{x_i} + \dots$$

- The spectral method is of an “infinite order”

$$\|u - u_{\text{exact}}\| = O(N^{-P}), \quad N \rightarrow \infty, \quad \text{non-continuous in } \frac{\partial^P u}{\partial x^P}$$

# Why Higher Order Methods?

Compare cos function, approximated by 3 points

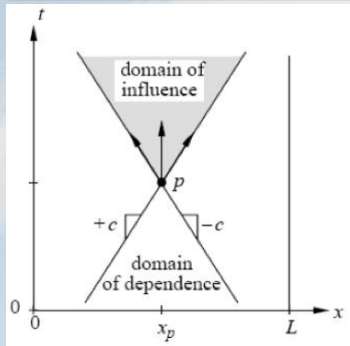

Can we not just add more points?

Higher-order methods when:

- High accuracy is required (increasingly so)
- Long time integration is required
- Memory becomes a bottleneck
- Scalability on parallel computers is important

# Hyperbolic Conservation Laws

$$\frac{\partial u}{\partial t} + \frac{\partial f}{\partial x} - g = 0$$

## Conservation:

Flux going out of one cell = Flux entering the next

# Higher-Order Finite Difference

Fourth order Finite difference:

$$\frac{\partial u_i}{\partial t} = - \left( \frac{-f_{i+2} + 8f_{i+1} - 8f_{i-1} + f_{i-2}}{12\Delta x} \right) + g_i$$

- Very fast, 5-point stencils
- Decoupling of domain in subdomains
- Structured grids
- Unnecessary small grid-spacing at higher latitudes

# Finite Volume method

## Integrated equation

$$\int \left( \frac{\partial u}{\partial t} + \frac{\partial f(u, x)}{\partial x} - g \right) dx = 0$$

$$\frac{\partial \langle u \rangle_k}{\partial t} + \frac{1}{\Delta x_k} [f^*]_{x_{k-\frac{1}{2}}}^{x_{k+\frac{1}{2}}} - \langle g \rangle = 0$$

- Discontinuous solution
- Conservative:  
Flux = continuous

Jump condition at  $x_{k+\frac{1}{2}}$ :  $f(\langle u_L \rangle) \neq f(\langle u_R \rangle)$

**Riemann problem:**  $f^* = \mathcal{H}(u_L, u_R)$  → Provides **upwinding**

# Second order Finite Volume Method

- Complex geometries on unstructured meshes
- Nested adaptive meshes
- Solution is defined in local manner
- Decoupling of domain in subdomains
- Natural upwinding couples cells
- Higher-order ( $>2$ ) tedious and costly (extended stencils)
- Grid smoothness requirements

# Finite Element Method – Continuous Galerkin

Equation is satisfied in global sense with solution defined nonlocally

$$\int \left( \frac{\partial u_h}{\partial t} + \frac{\partial f_h}{\partial x} - g \right) L_j(x) dx = 0, \quad u_h(x) = \sum_k^N u_k L_k(x)$$

- Continuity imposed
- $L_j$  has Value 1 in point  $j$ , Value 0 everywhere else

Global system of equations:  $M \cdot \frac{d\mathbf{u}_h}{dt} + S \cdot \mathbf{f}_h = M \cdot \mathbf{g}_h$

Mass matrix  $M$  :  $M_{ij} = \int_{\Omega} L_i(x)L_j(x)dx$

Stiffness matrix  $S$  :  $S_{ij} = \int_{\Omega} L_i(x) \frac{dL_j(x)}{dx} dx$

- High-order accuracy with compact flexible elements
- Complex geometries on unstructured meshes
- Implicit in time (Linear System Solver)
- Not well suited for problems with direction
- Everything is coupled through Mass matrix

# Discontinuous Higher-Order Methods

We want a method that combines

- the flexibility of **high-order** elements of FEM
- the **locality** and scalability of FVM

There exists a “family” of discontinuous higher-order methods with exactly these components

- **Discontinuous Galerkin Method**
- Spectral Volume Method
- **Spectral Difference Method**
- Flux Correction Method

# Idea behind Discontinuous Higher-Order Methods

- Solution is described within one element as a high-order function (borrowed from Finite Element Method)
  - ▶ Polynomial of order  $P$
  - ▶ Fourier series
  - ▶ Taylor series:  $\langle u \rangle, \frac{\partial u}{\partial x}, \frac{\partial^2 u}{\partial x^2}, \dots$
- Solution is defined locally on a per element basis
- Solution is not continuous across elements
- Flux is to be made continuous with Riemann solver (borrowed from Finite Volume Method)

P3 basis functions

# Observations

- Duplicated points at element interfaces (= more work)
- Solution does not look too nice as it is discontinuous
- Discontinuity does not affect high-order accuracy
- Discontinuity decouples elements (boundary conditions)
- Parallel efficiency outweighs more work

Interestingly: 1<sup>st</sup> order corresponds to Standard Finite Volume

P0 basis functions

# High-Order elements

- Extra points inside an element
- Effective increase in resolution
- Curved elements can align with coast lines
- Local mapping to standard element in parametric coordinates

$$\bar{J} = \frac{\partial(x, y)}{\partial(\xi, \eta)}$$
$$= \begin{bmatrix} x_\xi & y_\xi \\ x_\eta & y_\eta \end{bmatrix}$$

$$\text{Volume} \propto \det(\bar{J})$$

Parametric coordinates

# Lagrange polynomials

## Interpolation

$$q(\xi) = \sum_{j=1}^N Q_j L_j(\xi) \quad \text{with} \quad L_j(\xi) = \prod_{k \neq j} \frac{\xi - \xi_k}{\xi_j - \xi_k}$$

P1 (N=2)

P2 (N=3)

P3 (N=4)

## Differentiation

$$\frac{\partial q}{\partial \xi}(\xi) = \sum_{j=1}^N Q_j \frac{\partial L_j}{\partial \xi}(\xi) \quad \text{with} \quad \frac{\partial L_j}{\partial \xi}(\xi) = \sum_{i \neq j} \frac{1}{\xi_j - \xi_i} \prod_{\substack{k \neq i \\ k \neq j}} \frac{\xi - \xi_k}{\xi_j - \xi_k}$$

# Quadrilateral P2 (N=9)

$$q(\xi, \eta) = \sum_{j=1}^N Q_j L_j(\xi, \eta)$$

## Triangle P2 (N=6)

$$q(\xi, \eta) = \sum_{j=1}^N Q_j L_j(\xi, \eta)$$

# Element Integrals using quadrature

A **quadrature rule** approximates an integral using a weighted sum:

$$\int_{-1}^{+1} f(x) dx \approx \sum_{k=1}^n w_k^{\text{quad}} f(x_k^{\text{quad}})$$

- $x_k^{\text{quad}}$  are **quadrature points**
- $w_k^{\text{quad}}$  are **quadrature weights**

One of the most widely used families of quadrature rules is

**Gauss-Legendre quadrature:**

- Gauss-Legendre quadrature rule with  $n$  points and  $n$  weights can integrate a polynomial of degree  $2n - 1$  **exactly!**
- $x_k$  are distributed like the roots of the **Legendre polynomial**  $P_n(x)$
- $w_k$  are then:  $w_k = \frac{2}{(1-x_k^2)P_n'(x_k)^2}$

## Legendre polynomials:

$$P_0(x) = 1,$$

$$P_1(x) = x,$$

$$P_n(x) = \frac{2n-1}{n} P_{n-1}(x) x - \frac{n-1}{n} P_{n-2}(x)$$

$$P'_n(x) = \frac{n}{1-x^2} (P_{n-1}(x) - P_n(x) x)$$

## Gauss-Legendre quadrature points clustered towards $\pm 1$ :

5 points

10 points

15 points

20 points

The Gauss-Legendre quadrature points and weights have been extensively tabulated for  $x \in [-1, 1]$

Number of points ( $n$ )	Quadrature points	Quadrature weights
1	0	2
2	$-1/\sqrt{3}, 1/\sqrt{3}$	1, 1
3	$-\sqrt{3/5}, 0, \sqrt{3/5}$	5/9, 8/9, 5/9
$\vdots$	$\vdots$	$\vdots$

`quadrature.py`

: python-program provides points/weights with  $x \in [-1, 1]$  for **any**  $n$

Useful for **exact** integration of Lagrange polynomials.

**First interpolate to quadrature points!**

$n$	$2n - 1$
1	$\leq P_1$
2	$\leq P_3$
3	$\leq P_5$

# A Discontinuous Galerkin scheme

## Deriving the DG formulation

$$\frac{\partial u}{\partial t} + \nabla \cdot \mathbf{f} = 0$$

Integrate over entire domain  $\Omega$ :

$$\int_{\Omega} \left( \frac{\partial u_h}{\partial t} + \nabla \cdot \mathbf{f}_h \right) L_i(\mathbf{x}) d\mathbf{x} = 0$$

Rewrite as sum of element integration:

$$\sum_e \left( \int_e \frac{\partial u_h}{\partial t} L_i(\mathbf{x}) d\mathbf{x} + \int_e \nabla \cdot \mathbf{f}_h L_i(\mathbf{x}) d\mathbf{x} \right) = 0$$

Integrating by parts:

$$\sum_e \left( \int_e \frac{\partial u_h}{\partial t} L_i(\mathbf{x}) d\mathbf{x} + \oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^* \cdot \mathbf{n} d\mathbf{x} - \int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f} d\mathbf{x} \right) = 0$$

$$\sum_e \left( \int_e \frac{\partial u_h}{\partial t} L_i(\mathbf{x}) d\mathbf{x} + \oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^* \cdot \mathbf{n} d\mathbf{x} - \int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f} d\mathbf{x} \right) = 0$$

This can be satisfied for each element locally:

$$\int_e \frac{\partial u_h}{\partial t} L_i(\mathbf{x}) d\mathbf{x} + \oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^* \cdot \mathbf{n} d\mathbf{x} - \int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f} d\mathbf{x} = 0$$

**Riemann problem:**

$u_h$  is discontinuous at interfaces.

We need **conservation**.

**Numerical flux function  $\mathbf{f}^*$**  must be unique and provides element coupling

# Numerical Flux

**Question:** How should we choose  $\mathbf{f}^*$  on the “faces” of an element?

**Answer:** Just like in FV, numerical flux on a face should depend on data in the two neighbouring elements.

Let  $q^-$  (resp.  $q^+$ ) denote the value of  $q$  on the interior (resp. exterior) face of an element

Let  $\mathbf{n}^+$  (resp.  $\mathbf{n}^-$ ) denote the outward normal vector on the face of the “local” (resp. “neighbour”) element.

Hence  $\mathbf{n}^- = -\mathbf{n}^+$

Define “average” and “jump” operators:

$$\{\{q\}\} \equiv \frac{q^- + q^+}{2}$$

$$[[q]] \equiv \mathbf{n}^- q^- + \mathbf{n}^+ q^+ = \mathbf{n}^- (q^- - q^+)$$

# Numerical Flux

Roe scheme:

$$\mathbf{f}^* = \{\{\mathbf{f}\}\} + \frac{1}{2}|A| \llbracket u \rrbracket \quad \text{with} \quad A \equiv \frac{\partial \mathbf{f}}{\partial u}$$

Rusanov scheme:

$$\mathbf{f}^* = \{\{\mathbf{f}\}\} + \frac{1}{2}\lambda_{\max} \llbracket u \rrbracket \quad \text{with} \quad \lambda_{\max} \equiv \text{max wave speed}$$

Consider 1D linear advection:  $\mathbf{f} = au$ , and  $a$  is advection speed

$$\begin{aligned} \mathbf{f}^* &= \frac{1}{2}(au^- + au^+) + \frac{|a|}{2}(u^- - u^+) \\ &= u^-\left(\frac{a}{2} + \frac{|a|}{2}\right) + u^+\left(\frac{a}{2} - \frac{|a|}{2}\right) \\ &= \begin{cases} au^- & \text{if } a > 0 \\ au^+ & \text{if } a < 0 \end{cases} \end{aligned}$$

# Numerical Flux Properties

- Stability: upwind according to flow direction
- Conservative:  $\mathbf{f}^*$  is same computed when computed from the perspective of the neighbour element
- Consistent:  $\mathbf{f}^* \rightarrow \mathbf{f}$  when  $[[u]] \rightarrow 0$
- Rusanov scheme is much more dissipative than Roe scheme

## Finite Volume

The jump  $[[u]]$  is usually large, and **Roe** scheme is preferred.

## Discontinuous Higher-Order methods

The jump  $[[u]]$  can be very small, making the cheaper **Rusanov** scheme an attractive choice.

## Back to the DG scheme

$$\int_e \frac{\partial u_h}{\partial t} L_i(\mathbf{x}) \, d\mathbf{x} + \oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^* \cdot \mathbf{n} \, d\mathbf{x} - \int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f} \, d\mathbf{x} = 0$$

Consider the special P0 case where  $L_i(\mathbf{x}) = 1$ , and thus  $\nabla L_i(\mathbf{x}) = 0$ :

$$\int_e \frac{\partial u_h}{\partial t} \, d\mathbf{x} + \oint_{\partial e} \mathbf{f}^* \cdot \mathbf{n} \, d\mathbf{x} = 0$$

This is the definition of the Finite Volume scheme!

Although we started from the variational formulation like the **Finite Element Method**, the **Discontinuous Galerkin Method** can be reinterpreted as an extension of the **Finite Volume Method**

# Implementing a DG scheme

$$\int_e \frac{\partial u_h}{\partial t} L_i(\mathbf{x}) \, d\mathbf{x} = \int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f}(\mathbf{x}) \, d\mathbf{x} - \oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^*(\mathbf{x}) \cdot \mathbf{n} \, d\mathbf{x}$$

$$u_h(\mathbf{x}, t) = \sum_{j=1}^N u_j(t) L_j(\mathbf{x})$$

$$\sum_{j=1}^N \underbrace{\int_e L_i(\mathbf{x}) L_j(\mathbf{x}) \, d\mathbf{x}}_{M_{ij}} \frac{\partial u_j}{\partial t} = \underbrace{\int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f}(\mathbf{x}) \, d\mathbf{x}}_{\text{RHS}'_i} - \underbrace{\oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^*(\mathbf{x}) \cdot \mathbf{n} \, d\mathbf{x}}_{\text{RHS}''_i}$$

$$\mathbf{M}_e \frac{\partial \mathbf{U}_e}{\partial t} = \text{RHS}'_e - \text{RHS}''_e$$

$$\mathbf{M}_e \frac{\partial \mathbf{U}_e}{\partial t} = \mathbf{RHS}'_e - \mathbf{RHS}''_e$$

## Mass matrix

$$M_{ij}^e = \int_e L_i(\mathbf{x}) L_j(\mathbf{x}) d\mathbf{x}$$

## Computation in practice

Transform to parametric coordinates

$$M_{ij}^e = \int_e L_i(\boldsymbol{\xi}) L_j(\boldsymbol{\xi}) \left| \frac{d\mathbf{x}}{d\boldsymbol{\xi}} \right| d\boldsymbol{\xi}$$

Gaussian Quadrature

$$M_{ij}^e = \sum_q^{N_q} w_q L_i(\boldsymbol{\xi}_q) L_j(\boldsymbol{\xi}_q) |J_q|$$

$$\mathbf{M}_e \frac{\partial \mathbf{U}_e}{\partial t} = \mathbf{RHS}'_e - \mathbf{RHS}''_e$$

First RHS term

$$\mathbf{RHS}'_i = \int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f}(\mathbf{x}) \, d\mathbf{x}$$

## Computation in practice

Transform to parametric coordinates

$$\mathbf{RHS}'_i = \int_e \nabla L_i(\boldsymbol{\xi}) \bar{\mathbf{J}}^{-1} \cdot \mathbf{f}(\boldsymbol{\xi}) |J| \, d\boldsymbol{\xi}$$

Gaussian Quadrature

$$\mathbf{RHS}'_i = \sum_q^{N_q} w_q \nabla L_i(\boldsymbol{\xi}_q) |J_q| \bar{\mathbf{J}}_q^{-1} \cdot \mathbf{f}(\boldsymbol{\xi}_q)$$

Approximation of order of scheme:  $\mathbf{f}(\boldsymbol{\xi}) \approx \sum_{j=1}^N L_j(\boldsymbol{\xi}) \mathbf{f}(u_j)$

$$\mathbf{RHS}'_i \approx \underbrace{\sum_{j=1}^N \sum_q^{N_q} w_q L_j(\boldsymbol{\xi}_q) \nabla L_i(\boldsymbol{\xi}_q) |J_q| \bar{\mathbf{J}}_q^{-1}}_{S_{ij}} \cdot \mathbf{f}_j$$

Stiffness or Advection matrix

$$\mathbf{RHS}'_e \approx \mathbf{S}_e \mathbf{F}_e$$

Second RHS term

$$\mathbf{M}_e \frac{\partial \mathbf{U}_e}{\partial t} = \mathbf{RHS}_e^I - \mathbf{RHS}_e^{II}$$

$$\mathbf{RHS}_i^{II} = \oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^*(\mathbf{x}) \cdot \mathbf{n} \, d\mathbf{x}$$

## Computation in practice

Transform to parametric coordinates

$$\mathbf{RHS}_i^{II} = \sum_{f=1}^{N_f} \int_{\partial e_f} L_i(\boldsymbol{\xi}) \mathbf{f}^*(\boldsymbol{\xi}) \cdot \mathbf{n} \, |J_f| \, d\boldsymbol{\xi}$$

### Example in 1D

$$\mathbf{RHS}_i^{II} = L_i(\xi_L) \mathbf{f}^*(\xi_L) \cdot (-1) + L_i(\xi_R) \mathbf{f}^*(\xi_R) \cdot (+1)$$

$$\mathbf{RHS}_i^{II} = [L_i(\xi_L) \quad L_i(\xi_R)] \cdot \begin{bmatrix} -\mathbf{f}^*(\xi_L) \\ +\mathbf{f}^*(\xi_R) \end{bmatrix}$$

$$\mathbf{RHS}_e^{II} = \mathbf{H}_e \mathbf{F}\mathbf{n}_e^*$$

## Collecting the pieces

$$\mathbf{M}_e \frac{\partial \mathbf{U}_e}{\partial t} = \mathbf{RHS}'_e - \mathbf{RHS}''_e$$

$$\int_e \frac{\partial u_h}{\partial t} L_i(\mathbf{x}) \, d\mathbf{x} = \int_e \nabla L_i(\mathbf{x}) \cdot \mathbf{f}(\mathbf{x}) \, d\mathbf{x} - \oint_{\partial e} L_i(\mathbf{x}) \mathbf{f}^*(\mathbf{x}) \cdot \mathbf{n} \, d\mathbf{x}$$

Implemented as matrix products

$$\mathbf{M}_e \frac{\partial \mathbf{U}_e}{\partial t} = \mathbf{S}_e \mathbf{F}_e - \mathbf{H}_e \mathbf{F}_n^*$$

$$\frac{\partial \mathbf{U}_e}{\partial t} = \mathbf{M}_e^{-1} \mathbf{S}_e \mathbf{F}_e - \mathbf{M}_e^{-1} \mathbf{H}_e \mathbf{F}_n^*$$

$$\frac{\partial \mathbf{U}_e}{\partial t} = \mathbf{D}\mathbf{s}_e \mathbf{F}_e - \mathbf{D}\mathbf{h}_e \mathbf{F}_n^*$$

$$\mathbf{U}_e = [u_1, u_2, u_3, \dots, u_N] \quad \mathbf{F}_e = [\mathbf{f}(u_1), \mathbf{f}(u_2), \mathbf{f}(u_3), \dots, \mathbf{f}(u_N)]$$

# Demonstration 1D DGM

# Spectral Difference Method

## Why this name?

- **Spectral**: Higher-Order solution can be described as a Fourier Series
- **Difference**: Equations are solved in differential form, like Finite Difference

## Some properties

- Differential form of equations  $\rightarrow$  no quadrature necessary
- Unstructured grids / Complex geometries
- Compact stencil
- Shape functions provide higher order
- Upwinding between cells through Riemann solver
- Very intuitive approach

# Spectral Difference method

$$\frac{\partial q}{\partial t} + \nabla \cdot \mathbf{f} = 0$$

with mapping  $\bar{J} = \partial \bar{x} / \partial \bar{\xi}$

$$\frac{\partial \tilde{q}}{\partial t} + \tilde{\nabla} \cdot \tilde{\mathbf{f}} = 0$$

$$\tilde{q} = |J| q \quad \tilde{\mathbf{f}} = \begin{bmatrix} \tilde{f}_\xi \\ \tilde{f}_\eta \\ \tilde{f}_\zeta \end{bmatrix} = |J| \bar{J}^{-1} \mathbf{f}$$

# Spectral Difference method

Example: 1D 2<sup>nd</sup> order scheme  $\frac{\partial q}{\partial t} + \frac{\partial f}{\partial x} = 0$  with  $f = q$

- Solution  $q(\xi)$  is discontinuous and linear
- Goal is to get  $\frac{\partial}{\partial \xi}$  to 2<sup>nd</sup> order accuracy

# Spectral Difference method

Example: 1D 2<sup>nd</sup> order scheme  $\frac{\partial q}{\partial t} + \frac{\partial f}{\partial x} = 0$  with  $f = q$

- Extrapolate solution  $q(\xi)$  to “flux points”
- Compute flux
- Compute Riemann flux for conservation and upwinding between cells

# Spectral Difference method

Example: 1D 2<sup>nd</sup> order scheme  $\frac{\partial q}{\partial t} + \frac{\partial f}{\partial x} = 0$  with  $f = q$

- Extrapolate solution  $q(\xi)$  to “flux points”
- Compute flux
- Compute Riemann flux for conservation and upwinding between cells

# Spectral Difference method

Example: 1D 2<sup>nd</sup> order scheme  $\frac{\partial q}{\partial t} + \frac{\partial f}{\partial x} = 0$  with  $f = q$

- Flux is now a parabolic function
- Compute gradient of parabolic function in “solution points”

# Spectral Difference method

Example: 1D 2<sup>nd</sup> order scheme  $\frac{\partial q}{\partial t} + \frac{\partial f}{\partial x} = 0$  with  $f = q$

- Flux is now a parabolic function
- Compute gradient of parabolic function in “solution points”

# Stability of the Spectral Difference Method

## Question:

- Where should we put the solution points?
- Where should we put the flux points?

## Answer:

- Free to choose location of solution points
- Flux points however not:
  - ▶ Points on interface for element coupling
  - ▶ Stability analysis required (not covered)
  - ▶ One more point than solution points (in 1D)

## Flux point location

Roots of Legendre polynomial plus  $[\xi = -1, \xi = +1]$

# Solution / Flux Point distributions for SD

Second-order quadrilateral SD cells. Solution points (○) and  $\xi_1$ - (▼) and  $\xi_2$ -flux points (▲).

(a) General.

(b) Locally 1D.

(c) Most solution points at flux points, symmetrical.

(d) All solution points at flux points, asymmetrical.

# Implementing a SD method

- 1 Interpolate solution to all flux points (could be optimized depending on solution point distribution)

$$q_f = \sum_{j=1}^N q_j L_j^{\text{sol}}(\xi_f) \quad \rightarrow Q_{\text{fluxpts}}^e = \mathbf{I}_f Q^e$$

- 2 Compute numerical flux in interface flux points

$$\tilde{\mathbf{F}}_{\text{interface}}^e = |J| \bar{\bar{J}}^{-1} \mathbf{f}^*$$

- 3 Compute fluxes in internal flux points

$$\tilde{\mathbf{F}}_{\text{internal}}^e = |J| \bar{\bar{J}}^{-1} \mathbf{f}(Q_{\text{fluxpts}}^e)$$

- 4 Compute flux divergence

$$\frac{\partial \tilde{\mathbf{f}}}{\partial \xi} = \sum_{j=1}^{N_f} \tilde{\mathbf{f}}_j \frac{\partial L_j^{\text{flux}}(\xi_f)}{\partial \xi} \quad \rightarrow \tilde{\nabla} \cdot \tilde{\mathbf{F}}^e = \tilde{\mathbf{D}} \tilde{\mathbf{F}}^e$$

- 5 Update solution:

$$\frac{\partial Q^e}{\partial t} = \frac{1}{|J|} \tilde{\mathbf{D}} \tilde{\mathbf{F}}^e$$

# Demonstration 1D SDM

# Parallel efficiency

Discontinuous Higher-Order methods offer huge potential

- Matrix multiplications for near peak FLOP-rates  
I have shown you can write the entire method in matrix-vector notation
- Avoiding global communication  
Every element acts as a standalone domain with boundary conditions

- Mapping of problem to nested hierarchical computer architectures
  - ▶ MPI – distributed memory
  - ▶ OpenMP – shared memory
  - ▶ Accelerators (e.g. GPU) – matrix multiplications

# Spectral properties

Properties depend on choices for  
numerical flux, shape functions

Numerical damping of high wave numbers could make the method suitable for Implicit LES!

# Concluding

- Introduction to Higher-Order accuracy on unstructured meshes
- Implementations for hyperbolic conservation laws
- There is lots more to consider (diffusion terms, monotonicity, time stepping, curved elements)
- Parallel efficiency as main driving force
- Implicit LES properties are to be examined
