# What is the MJO?

- The MJO is a 40-50-day oscillation
- The MJO is a near-global scale, quasi-periodic eastward moving disturbance in the surface pressure, tropospheric temperature and zonal winds over the equatorial belt (4 to 8 m/s). Propagation speed is too slow for the MJO to be a Kelvin wave.
- The Madden-Julian Oscillation (MJO) is the dominant mode of variability in the tropics in time scales in excess of 1 week but less than 1 season.
- The MJO has its peak activity during Northern winter and spring.

## Theories for the onset of an MJO event

- **Local recharge/discharge processes** ( e.g. Hendon 1988, Blade and Hartmann 1993, Hu and Randall 1994...)
- **Upstream effects of circumnavigating waves** ( e.g. Knutson et al 1986, Knutson and Weickmann 1987, Lau and Peng 1987)
- **Stochastic forcing** (Wilson and Mak 1984, Neelin and Yu 1994, Yu and Neelin 1994)
- **Extratropical influences** (e.g. Lau and Peng 1987, Hsu et al 1990, Lin et al 2007, Ray et al 2010, Wedi and Smolarkiewicz 2010..)

# The Madden Julian Oscillation (MJO)

## Why is the MJO so important?

- Impact on the Indian and Australian summer monsoons (Yasunari 1979), Hendon and Liebman (1990)
- Impact on ENSO. Westerly wind bursts produce equatorial trapped Kelvin waves, which have a significant impact on the onset and development of an El-Niño event. Kessler and McPhaden (1995)
- Impact on tropical storms (Maloney et al, 2000; Mo, 2000)
- Impact on Northern Hemisphere weather

# Maritime Continent Barrier

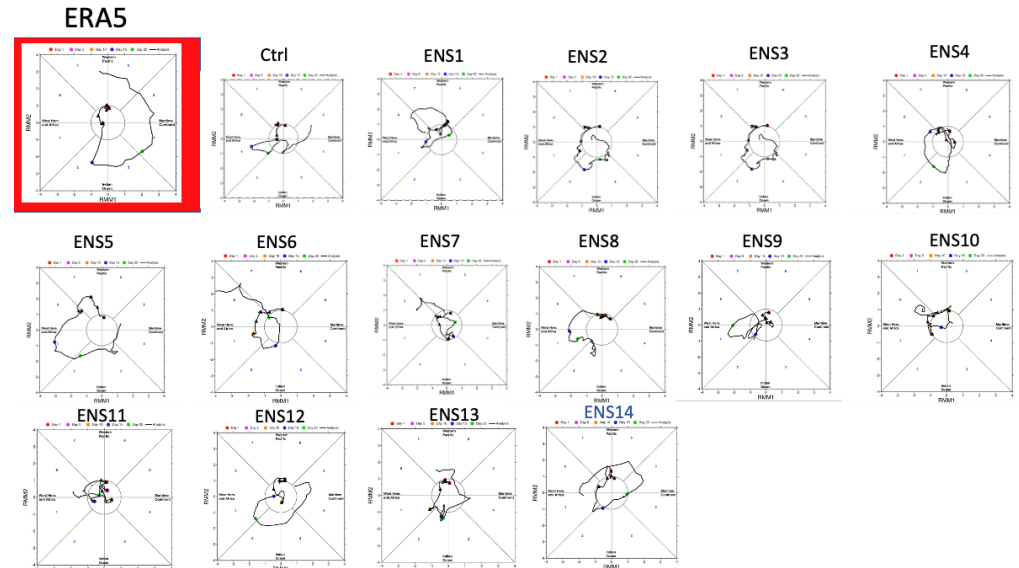

# Predicting the Onset of the MJO

Lim et al, 2018

Example: MJO event mid April 2019.  
Forecasts starting 10 days before onset

Forecasts with weak MJOs in initial conditions are less skillful

## Impact of ensemble generation

Ensemble forecasts of the MJO are more skillful than an individual ensemble member

# Simulation of the MJO in climate models

- Horizontal resolution: not important
- Vertical resolution: positive impact
- Air-sea coupling: Positive impact but not crucial
- Convection scheme: crucial

# Air-sea Interaction

# Impact of ocean/atmosphere coupling

- Uncoupled model has skill in predicting the evolution of the MJO

- Ocean-atmosphere increases significantly the MJO forecasting skill horizon

- Coupled model displays higher skill than atmospheric model forced by observed SSTs

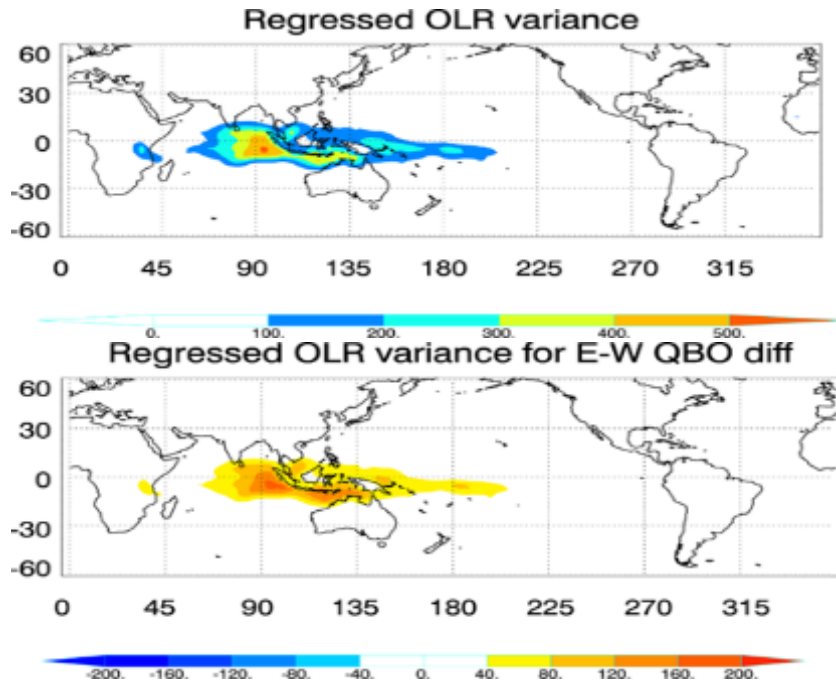

## MJO Bivariate Correlation

# Impact of the QBO?

MJO OLR Variance (DJF ) from reconstruction onto RMM

East waves 1-5 periods 30-80 days

Yoo and Son 2016

## 2 proposed mechanisms for impact on tropical convection

- 1) **Changes in static stability at tropopause:** more stable and lower tropopause in west phase > convection lower (and maybe less top heavy heating profile based on Nie and Sobel 2015)
- 2) **Changes in vertical shear of zonal wind at tropopause:** less shear at tropopause over equatorial IO/West Pac in easterly phase, favors increased convection in easterly phase?

# Impact of the QBO?

# Issues with Ocean Coupling

## Non linear interactions: North Atlantic SST mean errors impact subseasonal forecast skill

Correcting bias on SST over North Atlantic impacts the skill over Europe by improving MJO/NAO teleconnections

From Vitart and Balmaseda 2018

SST biases in western Atlantic can affect MJO teleconnection pathway

# ENSO Modulation of MJO teleconnections

# ENSO Modulation of MJO teleconnections

Lee et al. 2019

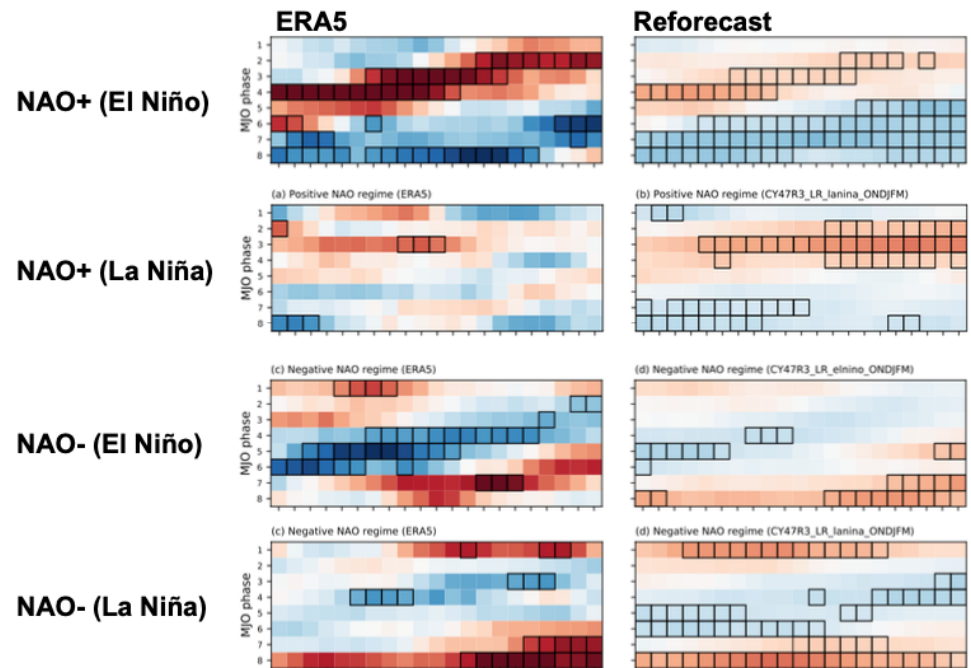

# MJO modulation by ENSO

## Forecasts underestimate the ENSO modulation of MJO-regime interactions

Lee et al. (2019) demonstrated that MJO-regime teleconnections depend on the ENSO background state.

1. Tropospheric teleconnection associated with increased NAO+ frequency following MJO phase 3/4 is stronger during El Niño years but suppressed during La Niña.
2. NAO- events following MJO phase 7/8 occurs later in the MJO phase cycle during La Niña years due to an enhanced stratospheric teleconnection pathway mediated by variations in the strength of the polar vortex.
3. Reforecasts do not reproduce this modulation.

Regime frequency conditioned on ENSO and the phase of the MJO at different lags (1980-2020)

Roberts et al. 2023

# Future Perspectives

- Coupled data assimilation might help improve MJO initialization
- Km-scale resolutions might be an opportunity to improve MJO prediction by removing some errors associated with convective parameterization.
- Machine learning brings opportunities to reduce model errors in the representation of the MJO and possibly produce more skillful MJO forecasts.

# Conclusions

- MJO is the main source of tropical variability between a week and a season
- Global Impact of the MJO including over Europe. Main source of sub-seasonal predictability.
- MJO prediction: success story – Significant improvement in the prediction of MJO over the past decade. Operational systems show predictive skill up to week 4
- Importance of SST coupling, although not crucial
- MJO activity is modulated by ENSO and QBO
- S2S models struggle to represent MJO teleconnections and their modulation by ENSO adequately.
- Machine Learning methods might help improve sub-seasonal prediction of the MJO and its impacts.
